

Coleo — One-Page Summary

What It Is

Distributed agent orchestration for software development. Coleo coordinates semi-autonomous AI arms through a central brain and a mail-based human interface.

Who It's For

Developers or teams who want multiple AI agents working on a codebase with human oversight.

What It Does

- Coordinates multiple AI arms and assigns tasks progressively via a central brain.
- Uses Maildir for human ↔ brain communication and task routing.
- Provides CLI commands to spawn/list arms, send tasks, and check status.
- Exposes a Hono REST + WebSocket API for arms, tasks, mail, and discoveries.
- Serves a React web observatory for monitoring and configuration.
- Persists system state in SQLite as the system of record.

How It Works (Architecture)

- Clients: CLI, web UI, and mail client connect to the system.
- Server: Hono API + WebSocket handle brain/arm state, tasks, mail, and discoveries.
- Brain: coordinates arms, builds context bundles, and manages task assignment.
- Arms: general-purpose agents that execute tasks under the brain's direction.
- Data: Maildir stores conversations; SQLite stores arms, tasks, activity, claims, and config.

How To Run (Minimal)

- Install dependencies: `bun install`
- Initialize state: `bun run src/cli/index.ts init`
- Start the brain: `bun run src/cli/index.ts brain run`
- Spawn an arm (optional first task): `bun run src/cli/index.ts arm spawn --name explorer --harness opencode`
